

ABSTRACT OF THE DISCLOSURE

The image pick-up apparatus is one in which a first image forming lens for forming as an image on a light-receiving surface a light entering from a first direction toward the light-receiving surface of an image pick-up device and a second image forming lens for forming as an image on the light-receiving surface a light entering from a second direction different from the first direction are mounted on a lens mount, and in which optical means for changing a direction of travel of at least one of the lights entering from these different directions to a direction perpendicular to the light-receiving surface is held in the lens mount.
